Q.1. The producer-consumer problem is an example of a multi-process synchronization problem. The producer and the consumer share a common fixed size buffer used as a queue.

The producer's job is to generate a piece of data, put it into the

 Shivam

buffer and start again. And at the same time, the consumer is consuming the data one piece at a time. The problem is to make sure that the producer won't try to add into the buffer if it's full and that the consumer won't try to remove ~~the~~ from an empty buffer.

Solⁿ to the problem:

As Producer-Consumer uses shared memory. We must have ~~to~~ available a buffer will reside in a region in a region of memory that is shared by the producer and consumer processes.

Also it can be done by inter-process communication, means semaphores. Inadequate solution ~~could~~ could result in a deadlock.

Q.4.

Q.2.

The banker's algorithm is a resource allocation and deadlock avoidance algorithm that tests for safety by simulating the allocation for pre-determined maximum possible amount of all resources, then makes an 's-state' check to test for possible activities, before deciding whether allocation should be allowed to continue.

It is deadlock detection algorithm.
